Word file representation in WordApplication

WordWriter represents a Microsoft Word document as a tree, similar to how Word itself represents a document. Most types of elements used with WordApplication correspond to entities that exist in an actual Word document, with some exceptions. Here is the recursive tree structure that WordWriter uses:

```
Document
|--Section
|--Paragraph
|--CharacterRun
|--InlineImage
|--Field (includes Hyperlinks and MergeFields)
|--Field Contents
|--(Recurses back to Paragraph subtree)
|--List
|--List
|--ListEntry
|--CharacterRun
|--CharacterRun
|--Field Contents
|--Field Contents
|--Field Contents
|--CharacterRun
|--Field Contents
|--Field Contents
|--CharacterRun
|--CharacterRun
|--Field Contents
|--Field Contents
|--Field Contents
|--CharacterRun
|--CharacterRun
|--Field Contents
|--CharacterRun
|--Field Contents
|--CharacterRun
|--CharacterRun
|--Field Contents
|--Field Contents
|--CharacterRun
|--CharacterRun
|--CharacterRun
|--CharacterRun
|--Field Contents
|--CharacterRun
|--Chara
```

The "Recurses back to ..." comments mean that the branch can continue with the same structure of elements as previously defined in the tree. For example, a TableCell can contain a Paragraph, List, and/or another Table, followed by the children those elements support, and so on.

As mentioned previously, not all elements in WordApplication correspond to actual elements in a Word document. For example, the Word file format does not have a list structure. A list item is simply a specialized paragraph with additional formatting. The List type was added to WordApplication to make it easier to work with lists programmatically.

By default, a new Document created using WordApplication.Create() contains the following elements:

```
Document
|
|--Section
|
|--Paragraph
|
|--CharacterRun
```

For more about inserting new elements into a Word document, see Inserting elements using WordApplication.
