

AutoFormatter

Description

When you import data to a table in your document, you can use the [AutoFormatter](#) interface to specify how the imported data should be formatted in the table. AutoFormatter contains a single method - [FormatCell](#) - which must be implemented in a class that you will use as an AutoFormatter. When you import data, set [DataImportProperties.AutoFormatter](#) to the class that you created.

C#

```
public abstract class AutoFormatter
```

vb.net

```
Public MustInherit Class AutoFormatter
```

Methods

Name	Description
FormatCell (TableCell, Int32, Int32, AutoFormatter.Edge)	This method must be implemented by the class you want to use as an AutoFormatter. Then, when you import data, you can use DataImportProperties.AutoFormatter to set the AutoFormatter for that data import.

Nested Classes

Name	Description
Edge	An AutoFormatter.Edge value specifies the location of a table cell in relation to the outer edge of the table.
